2021-2022 • Contest 2: Fibonacci Cypher • Senior Division

PROBLEM: Use this Fibonacci cypher to encode a given message into a list of numeric values or decode the numeric values into the original message.

The Fibonacci sequence can start with any two non-negative integers and every term after that is the sum of the two previous numbers. Therefore, if the first two numbers are 3 and 7, the sequence is 3, 7, 10, 17, 27, ... A Fibonacci cypher uses these numbers and an inputted 'key' (a lower-case letter in the alphabet) to encode a message into a list of numbers. Another person can decipher the message by knowing the 'key' that was used and the starting 2 Fibonacci numbers. For each character in the message, integers are generated by using the following steps:

1. Find the Fibonacci number with the same index as the character (e.g. using the sequence above, the 1st character uses the number 3 and the 5th character uses the number 27).
2. By using the inputted key, find a new letter that is offset by the Fibonacci number found in Step 1. Wrap around to the beginning of the alphabet if necessary (e.g. if the key = 'p' and the Fibonacci number is 17, then the new letter is 'g').
3. Find the number for each letter in the encoded message by adding the ASCII code of the character in the string to 3 times the ASCII code of the letter found in Step 2.

We guarantee the message will not be longer than 200 characters or numbers.

For this problem, there are two other things to consider:

- 1) All characters with an odd-numbered index starting with the 1st character in the string will shift characters to the right while all characters with an even-numbered index starting with the 2nd character will shift characters to the left.
- 2) At the beginning of every input, there will be an additional capital letter (E for encode or D for decode). If encoding, the message will be given to you. If decoding, the numbers will be given to you, each separated by a single space.

2021-2022 • Contest 2: Fibonacci Cypher • Senior Division

EXAMPLE: For the string “ACSL Sr-5 c2”, the initial Fibonacci numbers 3 and 7, and the letter ‘h’ as the ‘key’, the encoded numbers are found as shown:

Fibonacci offset	Character ASCII code	Calculation
$h + 3 = k = 107$	A = 65	$65 + 3 * 107 = 386$
$h - 7 = a = 97$	C = 67	$67 + 3 * 97 = 358$
$h + 10 = r = 114$	S = 83	$83 + 3 * 114 = 425$
$h - 17 = q = 113$	L = 76	$76 + 3 * 113 = 415$
$h + 27 = i = 105$	space = 32	$32 + 3 * 105 = 347$
$h - 44 = p = 112$	S = 83	$83 + 3 * 112 = 419$
$h + 71 = a = 97$	r = 114	$114 + 3 * 97 = 405$
$h - 115 = w = 119$	- = 45	$45 + 3 * 119 = 402$
$h + 186 = l = 108$	5 = 53	$53 + 3 * 108 = 377$
$h - 301 = s = 115$	space = 32	$32 + 3 * 115 = 377$
$h + 487 = a = 97$	c = 99	$99 + 3 * 97 = 390$
$h - 788 = z = 122$	2 = 50	$50 + 3 * 122 = 416$

The encoded message is “386 358 425 415 347 419 405 402 377 377 390 416”.

INPUT: There are 5 lines of data. Each line starts with either an E or a D followed by a single space. This will be followed by the two starting non-negative integers of the Fibonacci sequence separated by a single space, another single space, a single lower-case alphabetic character followed by a single space followed by the actual message to be encoded if you input an ‘E’ and the numeric codes if you input a ‘D’. Any typeable character on the keyboard except double quotes may be included in the message.

OUTPUT: For each line of data, print the integers separated by a single space that represent the encoded message OR print the string representing the decoded message.
